Supervisor Meeting Minutes
Meeting 3

Present: Matthew Chalmers, Jonas Leipner

Date: 13 October 2026

1 Achieved in Previous Week

Previous week: 6–13 October 2026

- Re-evaluated the constraints affecting dynamic code loading in production.
- Investigated the distinction between over-the-air patching and true runtime code loading.

2 Issues Discussed & Solutions Agreed

- **Shorebird limitation:** Shorebird can deliver code patches over the air, but the application must restart. It does not load new code dynamically inside an active game session.
- **True dynamic loading:** Runtime scripting through Lua or JavaScript, or the `dart_eval` Dart bytecode interpreter, is required for code to execute dynamically during a session.
- **`dart_eval` architecture:** `dart_eval` is sandboxed. An internal bridge is required to pass Flame game state into the sandbox, calculate values such as combat damage, and return validated results to Flame.
- **Research scope:** The project should compare plugin architectures with runtime dynamic code loading approaches used in commercial games.

3 Objectives for This Week

Upcoming week: 13–20 October 2026

- Test communication between the Flame Engine and the `dart_eval` sandbox.
- Research memory optimisation and dynamic loading practices in commercial game development.
